Learning

- Particularly in regulated environments, we need a reliable performance assessment before implementing a prediction model in practice.
- Example: disease diagnosis / prognosis based on clinical data
- Usually recommended strategy:

Evaluate a single final model on independent test data.

Evaluation

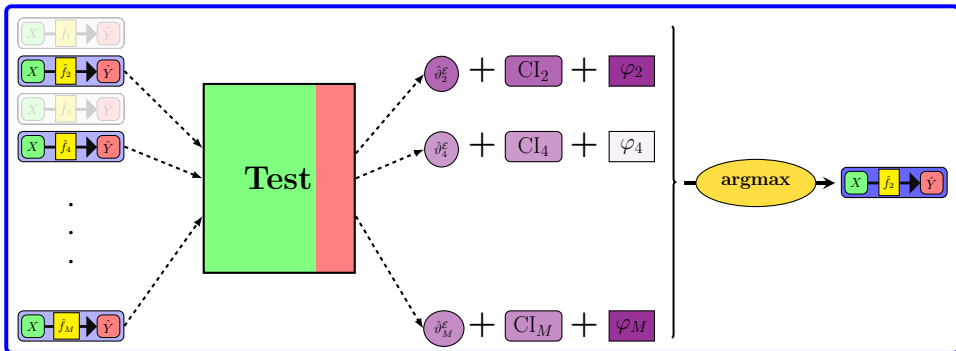

- Particularly in regulated environments, we need a reliable performance assessment before implementing a prediction model in practice.
- Example: disease diagnosis / prognosis based on clinical data
- Usually recommended strategy:

Evaluate a single final model on independent test data!

- Easy-to-use strategy, allowing for a reliable performance assessment and simple inference.
- However, we have no way to fix a bad model selection after having observed the test data.

Learning

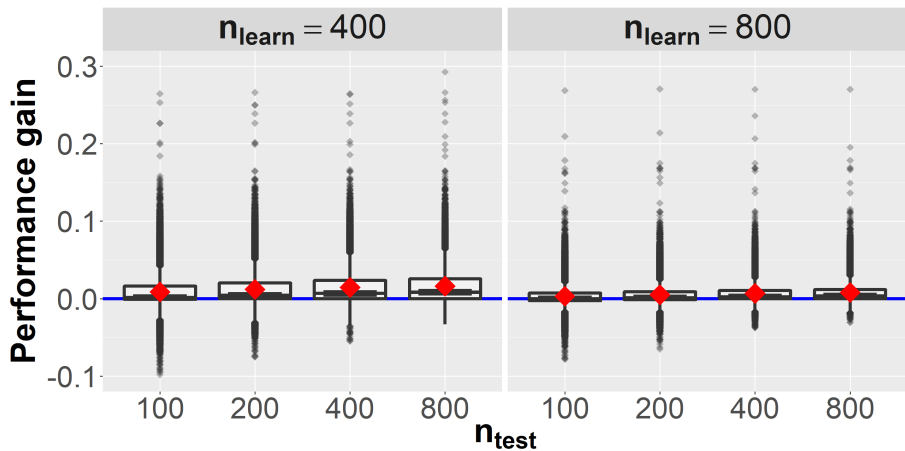

Evaluation

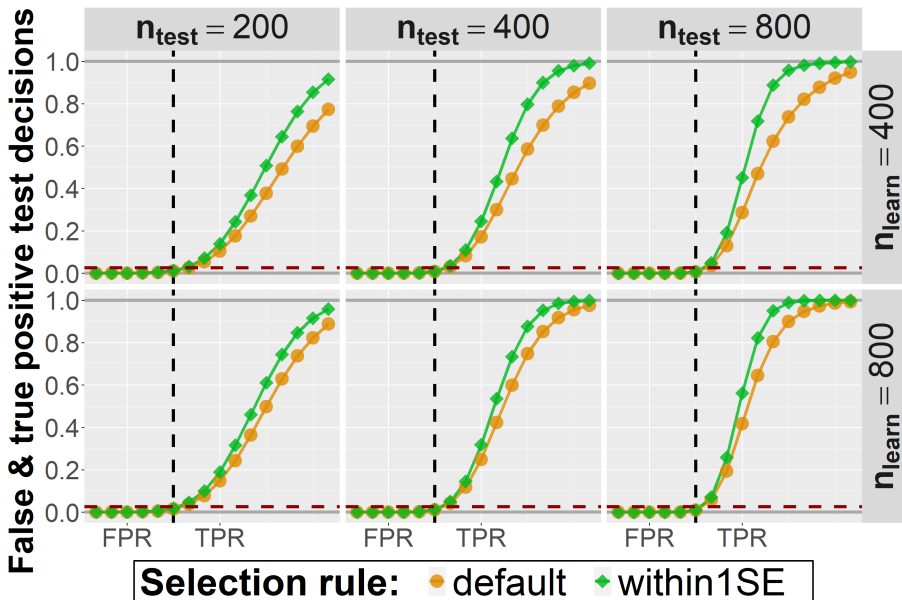

- **Idea:** simulate data and train, select and evaluate binary classifiers in different scenarios
 - 24 artificial classification tasks
 - 72,000 replications of complete ML pipeline
 - 28,800,000 distinct models (EN, CART, SVM, XGB)
- **Goal:** comparison of different evaluation strategies
 - **default:** best validation model only
 - **within 1 SE:** all models within 1 SE of best validation model

Simulation Results

Simulation Results

When in doubt, delay the final model choice to the test data.

- Improvements in model performance and probability to correctly identify a good model in all investigated scenarios.
- Adjustment for multiple comparisons via approximate parametric procedure taking into account model similarity (maxT-approach).

Questions & feedback welcomed!
