Graphical Models (GMs)

Idea: represent a multivariate function as the sum of many *simple* functions

$$\Theta_M = \underbrace{\sum_{(x_i, x_j) \in E} \theta_{ij}}_{\text{Pairwise potentials}} + \underbrace{\sum_{x_i \in X} \theta_i}_{\text{Unary potentials}} + \underbrace{\theta_\emptyset}_{\text{Constant term}}$$

Maximum a posteriori (MAP) assignment problem: find an assignment of all variables that maximizes the posterior probability

- $X = \{x_1, \dots, x_n\}$
- $x_i \in \{1, \dots, d_i\}, i = 1, \dots, n$

	6	2	1	7	8
	3			8	2
8				4	

Applications:

Linear and Semidefinite Programming Approaches

- Solving MAP is decision NP-complete
- Solving to optimality is not always practical

Goal: efficient tight *upper* and *lower* bounds

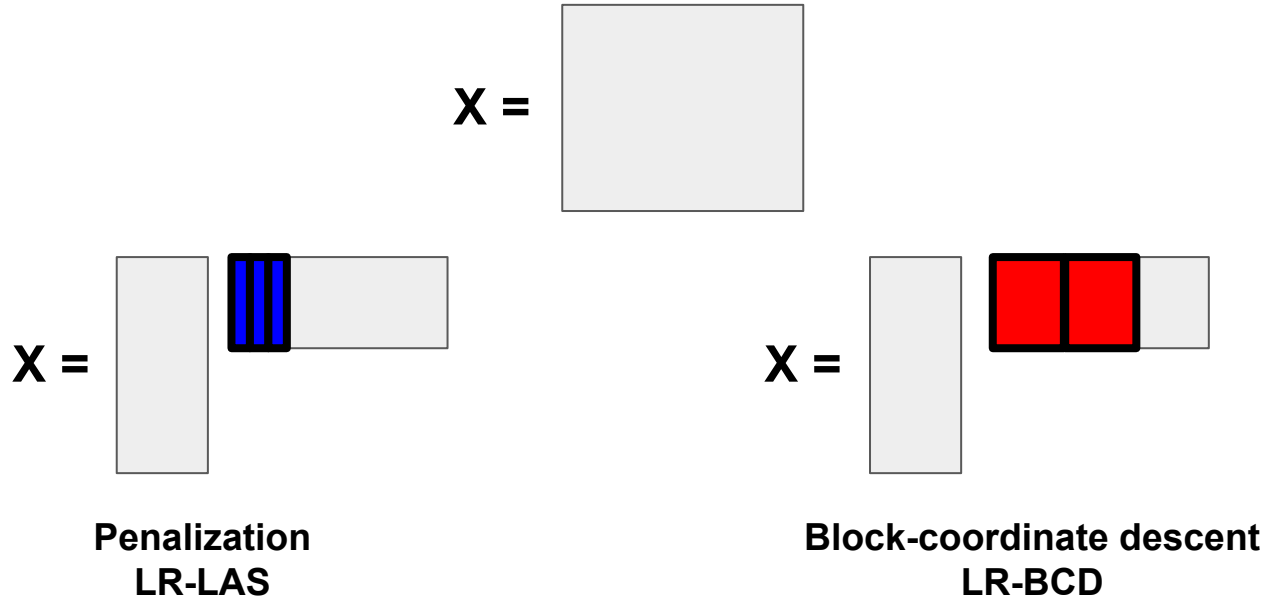

Linear Programming (LP)	Semidefinite Programming (SDP)
Convergent message passing (TRW-S)	Interior point methods
Scales well ✓	Quickly limited in size ✗
Loose bounds on hard instances ✗	Tight bounds ✓

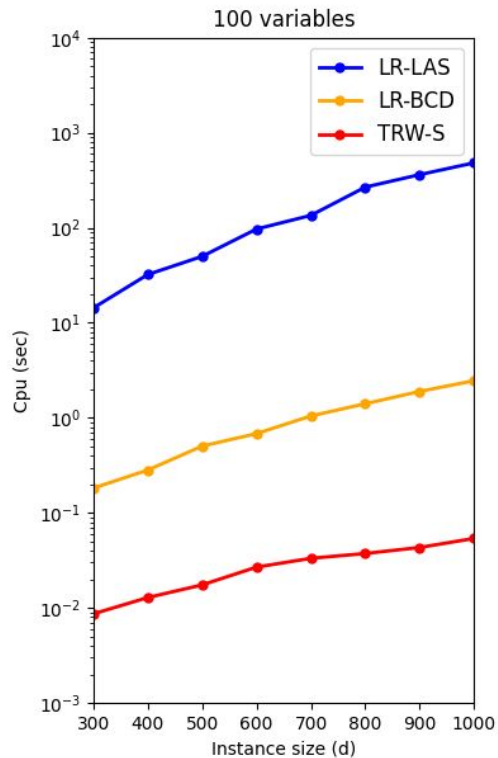

Efficient Semidefinite Programming Through Factorization

- Aim: efficient optimization of GMs with arbitrary potentials and # of states

Burer-Monteiro scheme

Exactly one state constraint

Upper and Lower Bounds

Random problems

Real instance: 34 296 vars

LP gap = [0, 128 878]

SDP gap = [102 900, 122 694]

Conclusion

Efficient MAP solving on arbitrary pairwise GMs
(# of states, potentials)

Far tighter bounds than LP / convergent message passing on dense hard instances

Scales to sizes not reachable by interior point solvers
