Optimal Batched Linear Bandits

This is a fully sequential decision problem!

ъ

Batch mode The player commits to a sequence of actions (*a batch of actions*) and observes the rewards *after all actions in that sequence are played*.

A single decision, batch size = 3

< 5

Batched linear bandits

Notations:

- T time horizon
- \mathcal{X} a fixed set of K actions
- ▶ θ^* an unknown parameter
- ► Rewards: $y_t = \langle x_t, \theta^* \rangle + \varepsilon_t$
- ► Regret: $R_T = E[\max_{x \in X} \sum_{t=1}^T \langle x x_t, \theta^* \rangle]$
- Batch complexity: number of batches

Our goal is to design batched algorithms that achieve optimal regret and batch complexity in different senses.

Asymptotic lower bound For an allocation $\alpha \in \mathbb{R}_{\geq 0}^k$ over actions we define the associated covariance matrix $H(\alpha) = \sum_{x \in X} \alpha(x) x x^T$. Let c^* be the solution to the following convex program,

$$\boldsymbol{c}^{*}(\boldsymbol{\theta}^{*}) \stackrel{\Delta}{=} \inf_{\boldsymbol{\alpha} \in \mathbb{R}^{k}_{\geq 0}} \sum_{\boldsymbol{x} \in \boldsymbol{X}} \boldsymbol{\alpha}(\boldsymbol{x}) \Delta(\boldsymbol{x}) \quad \text{s.t.} \quad \|\boldsymbol{x}\|_{\boldsymbol{H}^{-1}(\boldsymbol{\alpha})}^{2} \leq \frac{\Delta^{2}_{\boldsymbol{x}}}{2}, \forall \boldsymbol{x} \in \boldsymbol{\mathcal{X}}^{-} := \boldsymbol{\mathcal{X}} - \{\boldsymbol{x}^{*}\}, \quad (1)$$

In paper *The End of Optimism* [LS17], it is stated that any consistent algorithm π for the linear bandit setting with has regret $R_T(\theta^*, \pi)$ at least

$$\liminf_{T\to\infty}\frac{R_T(\theta^*,\pi)}{\log(T)}\geq c^*(\theta^*).$$

2 Research Goal

3 Algorithm and Analysis

Non-asymptotic

- minimax optimal regret, best instance-dependent regret bound
- batch complexity that matches existing lower bound, instance-dependent batch complexity

Non-asymptotic

- minimax optimal regret, best instance-dependent regret bound
- batch complexity that matches existing lower bound, instance-dependent batch complexity
- Asymptotic $T \to \infty$
 - asymptotically optimal regret
 - asymptotically optimal batch complexity

Non-asymptotic

- minimax optimal regret, best instance-dependent regret bound
- batch complexity that matches existing lower bound, instance-dependent batch complexity
- Asymptotic $T
 ightarrow \infty$
 - asymptotically optimal regret
 - asymptotically optimal batch complexity
- The first algorithm for linear bandits that simultaneously achieves the minimax and asymptotic optimality in regret with the corresponding optimal batch complexities!

Optimal Batched Linear Bandits Xuanfei Ren 14,

For any $\Delta\in[0,\infty)^k$ define $\textit{w}(\Delta)\in[0,\infty]^k$ to be a solution to the optimisation problem

$$\begin{split} \min_{\boldsymbol{w} \in [0,\infty]^k} \sum_{\boldsymbol{x} \in \mathcal{X}} w_{\boldsymbol{x}} \Delta(\boldsymbol{x}) \\ \text{s.t.} \quad \|\boldsymbol{x}\|_{H_{\mathbf{w}}^{-1}}^2 \leq \frac{\Delta_{\boldsymbol{x}}^2}{2}, \forall \boldsymbol{x} \in \mathcal{X}, \end{split}$$

where $H_w = \sum_{x \in \mathcal{X}} w_x x x^T$.

Sampling rule: use estimators to calculate $w(\hat{\Delta})$, then sample according to this proportion.

Chernoff's Stopping Rule (Generalized likelihood ratio test): If we find the best arm with probability at least 1 - 1/T, then stop to commit. Define

$$\begin{split} & Z(t) = \min_{x \neq \hat{x}^*} \frac{\hat{\Delta}_x^2}{2 \| \hat{x}^* - x \|_{H_t^{-1}}^2} \\ & \tau = \inf \bigg\{ t \in \mathbb{N}^* : Z(t) \geq \beta(\delta, t) \text{ and } \sum_{s=1}^t x_t x_t^T \geq c I_d \bigg\}, \end{split}$$

where τ is a stopping time. Choosing proper threshold β to make $\mathbb{P}(\tau < \infty, \theta^* {}^{\mathcal{T}}(x^* - \hat{x}^*_{\tau}) > 0) \leq \delta$.

Definition D-optimal design sampling allocation is given by:

$$\min_{\pi} \max_{\mathbf{x} \in \mathcal{X}} \|\mathbf{x}\|_{\mathcal{H}_{\pi}^{-1}}^{2}, \quad \mathcal{H}_{\pi} = \sum_{\mathbf{x} \in \mathcal{X}} \pi_{\mathbf{x}} \cdot \mathbf{x} \mathbf{x}^{\top}.$$

Pulling arms according to this special design leads to good concentration results like:

$$|\langle \hat{ heta} - heta^*, x
angle| \leq \sqrt{d \log(1/\delta) / \mathcal{T}_{arepsilon}}, \quad orall x \in \mathcal{X}$$

where the total pulling number is $\Theta(T_{\varepsilon})$.

Algorithm Design

The performance of our algorithm in each batch:

- 1. Exploration: D-optimal design; Estimation: calculate sampling proportion w
- Exploration: D-optimal design and according to the proportion;
 Estimation: calculate stopping statistics Z;
 Elimination: stopping rule
- 3. Exploration: D-optimal design; Elimination:

$$\mathcal{A} = \left\{ \mathbf{x} \in \mathcal{A} : \max_{\mathbf{y} \in \mathcal{A}} \langle \hat{\theta}, \mathbf{y} - \mathbf{x} \rangle \le 2\varepsilon_{\ell} \right\}$$

- 4. Repeat step 3 until $|\mathcal{A}| = 1$ or t = T
- 5. Exploitation: Commit to the estimated best arm

Algorithm design

Algorithm 1 Explore, Estimate, Eliminate, and Exploit (E⁴) **Input:** arm set \mathcal{X} , horizon T, parameters $\alpha, \delta, \gamma, \{T_1, T_2, \ldots\}, \{\varepsilon_1, \varepsilon_2, \ldots\}$ Initialization: $\ell = 1, t = 0, A = X$ 1: while t < T and $|\mathcal{A}| > 1$ do Exploration: 2: Find a multi-set in \mathcal{A} according to the D-optimal design in Definition 4.5 with $\Theta(T_{\ell})$ arms in total Pull arms in the D-optimal design multi-set 3: if $\ell = 2$ then 4: pull each arm $x \in \mathcal{A}$ for another min $\{w_x \cdot \alpha \log T, (\log T)^{1+\gamma}\}$ times 5: end if 6. Let b_{ℓ} be the total pulling number in the current batch 7: Estimation: 8: Update least squares estimators $\hat{\theta}, \hat{x}^*, \hat{\Delta}$ and calculate

 $\begin{cases} w(\hat{\Delta}) \text{ according to Definition 4.1} & \text{if } \ell = 1\\ Z(b_2) \text{ according to } (4.2) & \text{if } \ell = 2 \end{cases}$

9: Elimination:

Update the active action set according to

$$\begin{cases} \mathcal{A} = \{\hat{x}^*\} \text{ if stopping rule (4.4) holds } & \text{if } \ell = 2\\ \mathcal{A} = \left\{ x \in \mathcal{A} : \max_{y \in \mathcal{A}} \langle \hat{\theta}, y - x \rangle \leq 2\varepsilon_\ell \right\} & \text{if } \ell = 3, 4, \dots \end{cases}$$

10: $\ell = \ell + 1, t = t + b_{\ell}$ 11: end while 12: Exploitation: pull arm $x \in \mathcal{A}$ for T - t times

Define

$$\mathcal{T}_1 = \{ T_1 = (\log T)^{1/2}, T_2 = (\log T)^{1/2}, T_3 = (\log T)^{1+\gamma}, T_\ell = T^{1-\frac{1}{2\ell-3}}, \ell \geq 4 \}.$$

• When $\{T_\ell\}_{\ell=1}^{\infty} = \mathcal{T}_1$, our algorithm achieves

 $\textit{Regret}(\textit{T}) \leq \tilde{\textit{O}}(\sqrt{\textit{dT}}),$

with at most $O(\log \log T)$ batches.

Define

$$\mathcal{T}_2 = \{ T_1 = (\log T)^{1/2}, T_2 = (\log T)^{1/2}, T_3 = (\log T)^{1+\gamma}, T_\ell = d\log(kT^2) \cdot 2^{\ell-3}, \ell \ge 4 \}.$$

• When $\{T_{\ell}\}_{\ell=1}^{\infty} = \mathcal{T}_2$, our algorithm achieves $\tilde{O}(\sqrt{dT})$ regret and

Algorithm and Analysis

$$Regret(T) \le O\left((\log T)^{1+\gamma} + \frac{d\log(KT)}{\Delta_{\min}}\right) = \tilde{O}\left(\frac{d}{\Delta_{\min}}\right),$$

with at most $\textit{O}(\log \textit{T})$ batches and in expectation $\textit{O}(\log(1/\Delta_{\min}))$ batches.

▶ In the asymptotic setting, when $T \to \infty$, our algorithm with $\{T_\ell\}_{\ell=1}^{\infty}$ equaling \mathcal{T}_1 or \mathcal{T}_2 achieves asymptotic optimality defined above, i.e.,

$$\limsup_{T\to\infty}\frac{\operatorname{Regret}(T)}{\log(T)}\leq c^*,$$

with 3 batches in expectation.

We prove:

Theorem (Batch complexity lower bound) If an algorithm achieves asymptotic optimality, then on all bandit instances, it must have at least 3 batches in expectation as $T \rightarrow \infty$.

The batch complexity of our algorithm matches this lower bound!
